Abstract: An imperfection sensitivity analysis of cold-formed steel members in compression is presented. The analysis is based on Koiter’s approach and Monte Carlo simulation. If the modes interaction is correctly accounted, than the limit load and the erosion of critical buckling load can be easily evaluated. Thousands of imperfection can be analysed with very low computational cost and an effective statistical evaluation of limit performance can be carried out. The analysis is done on pallet rack uprights in compression, based on an intensive experimental study carried out at the Politehnica University of Timisoara.

Key words: Koiter Asymptotic Approach, Instability Problems, Thin-Walled Cold-Formed Steel Members, Imperfection Sensitivity Analysis, Monte Carlo

1. INTRODUCTION

The finite element implementation of Koiter’s asymptotic approach allows to evaluate the pre-critical and initial post-critical behaviour of slender elastic structures, also in the presence of strong non-linear for pre-critical and in the case of interactive buckling (Casciaro, 2005). The method is considered very attractive for its advantages in respect to path-following approach (Riks, 1979). These consist in an accurate post-buckling analysis and in an efficient imperfection sensitivity analysis with low computational cost (Casciaro, 2005). The main difficulties arise in the availability of geometrically coherent structural model and in an accurate evaluation of their high order energy variations (Garcea et al., 2012a, 2012b). The use of co-rotational formulation, within a mixed formulation, allows to have a general finite element implementation of Koiter analysis (Zagari et al., 2013).

Our recent technology (Barbero et al., 2014, 2015), in terms of numerical implementation is applied for the evaluation of performance of slender cold-formed steel members especially for the case of modal interaction. In particular, an efficient and robust imperfection sensitivity analysis is performed. Using a Monte Carlo simulation, for a random sequence of imperfections assumed with the shape as linear combination of buckling modes, the equilibrium paths for the imperfect structures are recovered. The load carrying capacity is evaluated statistically. The worst imperfections are detected and the limit load is obtained, allowing the evaluation of erosion of critical bifurcation load (Dubina and Ungureanu, 2014b). The described implementation is called quadratic algorithm. The method is based on the expansion of the potential energy, in terms of load factor λ and buckling mode amplitudes ξi, which is characterized by fourth-order accuracy. It provides an approximation of the equilibrium path by performing the following steps:

1. The fundamental path is obtained as a linear extrapolation, from a known equilibrium configuration:

   \[ u^f[\lambda] = \lambda \hat{u} \]  

   where \( u \) is the field of configuration variables in terms of stress and displacement and \( \hat{u} \) is the tangent obtained as a solution of the linear equation

   \[ \Phi''[\lambda_0 \lambda_j \lambda_i] \hat{\nu}_i \delta u = 0, \ \forall \delta u \in J. \]  

   2. A cluster of buckling loads \( \{\lambda_0 \ldots \lambda_m\} \) and associated buckling modes \( \{\hat{\nu}_1 \ldots \hat{\nu}_m\} \) are defined along \( u^f[\lambda] \) by the critical condition

   \[ \Phi''[u^f[\lambda]] \hat{\nu}_i \delta u = 0, \ \forall \delta u \in J. \]  

   Buckling loads are considered to be sufficiently close to each other to allow the following linearization

   \[ \Phi''[\lambda_b] \hat{\nu}_i \delta u + (\lambda_j - \lambda_b) \Phi''[\lambda_b] \hat{\nu}_i \hat{\nu}_j \delta u = 0, \ \forall \delta u \in J. \]  

   \( \lambda_b \) being an appropriate reference value of \( \lambda \) (e.g. the first of \( \lambda_i \) or their mean value). Normalizing we obtain \( \Phi''[\lambda_b] \hat{\nu}_i \hat{\nu}_j = \delta_{ij} \), where \( \delta_{ij} \) is Kroneker’s symbol.

   3. The tangent space \( J \) is decomposed into the tangent \( V \equiv \{\hat{\nu}_i = \sum_i \hat{\nu}_i \hat{\nu}_i\} \) and orthogonal \( W \equiv \{w: \Phi''[\lambda_b] \hat{\nu}_i w = 0\} \) subspaces so that \( J = V \Theta W \). Denoting \( \xi_0 = \lambda \) and

2. THEORETICAL BACKGROUND

A summary of the FE asymptotic analysis proposed by Casciaro et al. is presented (Casciaro, 2005; Garcea et al., 2014a, 2014b).
\[ \dot{\nu}_o = \ddot{\nu}, \] the asymptotic approximation for the required path is defined by the expansion

\[ u[\lambda, \xi_k] = \sum_{i=0}^{m} \xi_i \nu_i + \frac{1}{2} \sum_{i=0}^{m} \xi_i \xi_j w_{ij} \]  

where \( w_{ij} \) are the quadratic corrections introduced to satisfy the projection of eqn. (1) onto \( W \) and obtained by the linear orthogonal equations

\[ \phi''_b w_{ij} \delta W = - \phi''_b \dot{\nu}_i \dot{\nu}_j \delta w, \delta w \in W \]  

where, because of the orthogonality condition, \( w_{ij} = 0 \).

4. The following energy terms are computed for \( i,j,k = 1 \ldots m \):

\[ \mu_k[\lambda] = \frac{1}{2} \lambda^2 \phi''_b \ddot{\nu}_i \ddot{\nu}_k + \frac{1}{6} \lambda^2 (\lambda - 3 \lambda_b) \phi''_b \ddot{\nu}_i \ddot{\nu}_k \]

\[ A_{ijk} = \phi''_b \dot{\nu}_i \dot{\nu}_j \dot{\nu}_k \]  

\[ B_{ijk} = \phi''''_b \ddot{\nu}_i \ddot{\nu}_j \ddot{\nu}_k - \phi''_b (w_{ij}w_{hk} + w_{ih}w_{jk} + w_{ik}w_{jh}) \]

\[ C_{ijk} = \phi'''_b \dot{\nu}_i \dot{\nu}_j \dot{\nu}_k \]  

where the implicit imperfection factors \( \mu_k \) are defined by the 4th order expansion of the unbalanced work on the fundamental (i.e. \( \mu_k[\lambda] = (\lambda \ddot{\nu} - \phi''(\lambda \ddot{\nu})) \ddot{\nu}_k \)).

5. The equilibrium path is obtained by satisfying the projection of the equilibrium eqn. (1) onto \( W \). According to eqns. (7) and (8), we have

\[ (\lambda_k - \lambda) \xi_k - \lambda_b \left( \lambda - \frac{\lambda_b}{2} \right) \sum_{i=1}^{m} \xi_i C_{ijk} + \frac{1}{2} \sum_{i,j=1}^{m} \xi_i \xi_j A_{ijk} + \frac{1}{2} (\lambda - \lambda_b)^2 \sum_{i=1}^{m} \xi_i B_{0ijk} \]

\[ \frac{1}{2} (\lambda - \lambda_b) \sum_{i,j=1}^{m} \xi_i \xi_j B_{0ijk} + \frac{1}{6} \sum_{i,j,k=1}^{m} \xi_i \xi_j \xi_k B_{ijk} + \mu_k[\lambda] = 0, \quad k = 1 \ldots m \]

Equation (8) corresponds to a highly nonlinear system in the \( m+1 \) unknowns, \( -\xi_i \), and can be solved using a standard path-following strategy. It provides the initial post-buckling behaviour of the structure including modal interactions and jumping-after-bifurcation phenomena (see Fig. 1).

![Fig. 1. Interactive buckling for coincident/nearby coincident buckling loads](image)

In the analysis of thin-walled members the characterization of imperfection is often difficult. The presence of imperfections changes some aspects of structural response and often causes an erosion of the load carrying capacity, especially in the interactive buckling range. In the asymptotic algorithm the presence of imperfections expressed by a load \( p[\lambda] \) and/or an initial displacement \( \ddot{\nu} \), affect eqn. (9) only with the imperfection term \( \mu_k[\lambda] \) that becomes (Casciaro, 2005).

\[ \mu_k[\lambda] = \frac{1}{2} \lambda^2 \phi''''_b \ddot{\nu}_i \ddot{\nu}_k + \frac{1}{6} \lambda^2 (\lambda - 3 \lambda_k) \phi''_b \ddot{\nu}_i \ddot{\nu}_k \]

The aim of the imperfection sensitivity analysis is to link the presence of geometrical and load imperfections to the reduction in the limit load. For structures presenting coupled buckling even a small imperfection in loading or geometry can represent a significant reduction in ultimate load with respect to the bifurcation load (Garcea et al., 2014a, 2014b). So an effective safety analysis should include an investigation of all possible imperfection shapes and sizes to identify the worst imperfection cases.

3. NUMERICAL RESULTS

On the following, an imperfection sensitivity analysis for upright pallet racks in compression, with and without perforations, is presented. The geometry of the cross-section is shown in Fig. 2, while details related to cross-section, perforations, lengths, material, experimental tests and numerical simulations can be found in (Crisan et al., 2012a, 2012b). The member will be denoted on the following as RS125×3.2, as in (Crisan et al., 2012a, 2012b). The RS125×3.2 specimen has a perforated-to-brut cross-section ratios, \( A_N/A_B \), of 0.806.

![Fig. 2. (a) Geometry of RS125×3.2 section with and without perforations (dimensions are expressed in mm); (b) Perforations details](image)
fications have been considered. In particular, the total imperfection
\( \tilde{u} \), as shown in eqn. (10), is assumed to be:

\[
\tilde{u} = \tilde{u}^g + \tilde{u}^d
\]  (10)

where \( \tilde{u}^g \) and \( \tilde{u}^d \) are the global and distortional/local imperfections, that are assumed as linear combinations of global \( \tilde{v}^g_i \) and distortional/local \( \tilde{v}^d_i \) buckling modes, that is:

\[
\tilde{u}^g = \sum_i r_i \tilde{v}^g_i \quad i = 1 \ldots m^g
\]

\[
\tilde{u}^d = \sum_i r_i \tilde{v}^d_i \quad i = 1 \ldots m^d
\]  (11)

In eqn. (11) \( r_i \) are random number, while \( m^g \) and \( m^d \) are the number of global and distortional/local buckling modes. The maximum values of \( \widetilde{u}^g_{\text{max}} \) and \( \widetilde{u}^d_{\text{max}} \) are assumed to be smaller than the assumed tolerances (see Fig. 3), i.e. \( \widetilde{u}^g_{\text{max}} < \frac{L}{1000} \) for global imperfection and \( \widetilde{u}^d_{\text{max}} < 1.5 t \) for distortional one, where \( L \) and \( t \) are the length of the upright pallet rack and the thickness of the cross-section.

![Distortional and global imperfections for numerical analysis](image)

For each length, the first four buckling modes are considered. For the simulation the rack was considered pinned at one end and simply supported at the other one. For the pinned end, all three translations together with rotation along the longitudinal axis were restrained. For the simply supported end, the translation along the section axis together and the torsional rotations were restrained. The details of the mesh are reported in Fig. 4.

![Details of the mesh for RS125×3.2 brut and net section](image)

For the range of lengths under evaluation, eight distortional buckling modes and two global buckling modes have been detected as shown in Tabs. 1 and 2 and Figs. 5 and 6.

It is easy to observe from Tabs. 1 and 2 that the interactive buckling range is between (2000 ... 2500) mm, confirming the values obtained in (Crisan et al., 2012a).

Koiter Asymptotic Analysis of Thin-Walled Cold-Formed Steel Members

Fig. 6. Distortional $d_1$, $d_2$, ... $d_8$ and global $e_1$, $e_2$ buckling modes for RSN125×3.2 net section in the range $L = 1400$ ... 2500 mm

Fig. 7 presents the buckling loads versus the lengths of the upright members with and without perforations. The range corresponding to global/distortional interactive buckling can be clearly seen, as stated above.

Fig. 7. Buckling load vs. corresponding length for the R125×3.2 brut (B) and net (N) sections

Fig. 8 presents the first four buckling modes for the 2200 mm length, while Fig. 9 the quadratic corrections for the same length, as was defined by eqn. (5). Note that, the aim of the paper is to find the worst imperfection case. Then, the real shape of the imperfection is not required and only the linear combinations of buckling modes are considered. Anyway, the validation of numerical model has been done according to the measured data in (Crisan et al., 2012a).

On the second step, the post-buckling analysis has been performed considering the four buckling modes presented in Tabs. 1 and 2, for the members with lengths $L = 1400$ ... 2500 mm. The changing of the buckling load and shape at varying lengths is shown in Fig. 5 for brut cross-sections and Fig. 6 for the section with perforations.

The multimodal analysis has been performed considering the four buckling modes presented above. Five hundred random
geometric imperfections have been generated with a very low computational cost. The results, in terms of limit load/ displacements, for both brut and net cross-section, are shown in Fig. 10, while the worst imperfections and limit load shapes, for the length $L = 2200$ mm, are shown in Fig. 11.

Fig. 10a. Brut section RS125x3.2 with length of 2200 mm: equilibrium paths $\lambda$ versus $u$. The displacement components $u_1$, $u_2$, and $u_3$ are measured in the point of the middle of the upright pallet rack section

Fig. 10b. Net section RS125x3.2 with length of 2200 mm: equilibrium paths $\lambda$ versus $u$. The displacement components $u_1$, $u_2$, and $u_3$ are measured in the point of the middle of the upright pallet rack section

The frequency for the limit loads and its probability distribution are reported in Fig. 12 (a and b). For the specimens with strong buckling interaction, the values are very close to the peak of the distribution. The length with strong interaction are also clearly highlighted, i.e. $L = 2200$ mm. The average time required for the steps 1 to 4 have been studied (Barbero et al, 2015), and they remain of the order of seconds. This could allow users to run Monte Carlo simulations to account for other types of imperfections, i.e. load imperfection, residual stress, a.s.o., in order to obtain even more realistic evaluations of structural performance.

Fig. 11. Section RS125x3.2, brut and net, with the length of 2200 mm: (a) initial shapes for worst imperfection amplified by factor 5.0, (b) deformed shapes at limit load for worst imperfection amplified factor 2.5

4. EVALUATION OF $\psi$ EROSION FACTORS

It is very well known that in the case of an ideal structure, the theoretical equilibrium bifurcation point and corresponding load, $N_{cr}$, are observed at the intersection of the pre-critical (primary) force-displacement curve with the post-critical (secondary) curve (see Fig. 13). For a real structure, affected by a generic imperfection, $\delta_0$, the bifurcation point does not appear anymore and, instead, the equilibrium limit point is the one characterizing the ultimate capacity, $N_u$, of the structure. The difference between $N_{cr}$ and $N_u$ represents the Erosion of the Critical Bifurcation Load, due to the coupling and imperfections (Dubina, 2001).

In almost all practical cases, the mode interaction, obtained by coupling of a local instability with an overall one, is a result of design (e.g. calibration by design of mechanical and geometrical properties of member), and has a nonlinear nature.

Due to the imperfections, an interaction erosion of critical bifurcation load occurs. This erosion is maximum in the coupling point vicinity. For members, an interactive slenderness range, in which sensitivity to imperfections is increased, may be identified. Depending on imperfection sensitivity, classes of interaction types, characterized by specific levels of erosion intensity, may be defined (Gioncu, 1994).

Being given a member in compression let assume two simultaneous buckling modes which might couple (see Fig. 14).

![Fig. 13. Critical and post-critical behaviour](image)

Fig. 13. Critical and post-critical behaviour

The perfect member is prone to interactive buckling, with the critical buckling load, $N_{cr}$, while the actual member with the ultimate load, $N_u$. The erosion coefficient, $\psi$, can be expressed as follows:

$$\psi = 1 - \frac{\bar{N}_u}{\bar{N}_{cr}}$$

and

$$\bar{N}_u = (1 - \psi)\bar{N}_{cr}$$

The Monte Carlo simulation also allows to found the worst imperfection case, as shown in Fig. 10, and to evaluate the erosion as shown in Fig. 15 (Dubina, 2001). The load carrying capacity is evaluated statistically. The worst imperfections are detected and the limit load is obtained so allowing the evaluation of erosion of critical bifurcation load according to eqn. (10). The evaluation of erosion is shown in Fig. 15. The maximum erosion has been detected for the specimens corresponding to the length $L = 2200$ mm.

![Fig. 15. The minimum limit load normalized to the cross-section capacity for brut (B) and net (N) section](image)

Fig. 15. The minimum limit load normalized to the cross-section capacity for brut (B) and net (N) section

The buckling modes that provide the maximum erosion and their participation are presented in Tab. 3. In Figs. 5 and 6 are defined these buckling modes.

Once, evaluated the worst imperfections the sensitivity curves have been recovered (see Fig. 15). The figure shows that brut sections have a higher limit load than the net sections, however the slope of sensitivity curves is the same.

Finally, it can be observed that based on the above parametric study, the obtained maximum erosion are of 0.45 for the brut section (B) and 0.42 for the net section (N). In a direct comparison with the results obtained via ECBL approach (Dubina, 2001), it
can be observed they are in a good agreement with the ones obtained by Ungureanu and Dubina (2013), i.e. of 0.44 for the net section, but for a combination of imperfections ($\tilde{u}_{\text{max}} = L/750$ and $\tilde{u}_{\text{max}} = 1.5$ t). The erosions obtained by Crisan et al. (2012b) via ECBL approach, i.e. 0.387 for the brut section and 0.395 for the net section, are also close to the ones presented above but have been obtained for different combination of imperfections, i.e. ($\tilde{u}_{\text{max}} = L/1000$ and $\tilde{u}_{\text{max}} = 1$ t).

5. CONCLUSIONS

An imperfection sensitivity analysis using Koiter’s approach and the Monte Carlo method has been applied for the evaluation of imperfection sensitivity of cold-formed upright members for pallet racks in compression, with and without perforations. The analysis allows to evaluate the limit loads, the erosion of the theoretical buckling due to both imperfections and the mode interaction. The main strengths of the proposed methodology are the ability to analyse thousands of random imperfections in a short time, with very low computational cost, to find the worst imperfections and to provide an accurate evaluation of the limit load and of the erosion of buckling load, with respect to theoretical case, due to buckling mode interaction.

Once again is shown and validated that the ECBL approach is an excellent and practical method that allows for the evaluation of $\psi$ erosion coefficients and $\alpha$ imperfection factors, as result of interactive buckling.
